

SOUTH COAST CONSERVATION PROGRAM

Protecting and Restoring at Risk Species and Ecological Communities on BC's South Coast

Published on *South Coast Conservation Program* (<http://sccp.ca>)

Vancouver Island Beggarticks

Bidens amplissima

A member of the family Asteraceae (“asters”), this wetland annual has over 85% of its global range in BC. The genetic makeup of *B. amplissima* suggests that it only recently evolved from two closely related species – “nodding” and “three-parted” beggarticks, and may be the result of hybridization. Once thought to be endemic only to extreme southwestern BC, this species has recently been discovered in Washington State.

Characteristics

Height to approximately 1 m. An annual herb with erect branching stems. Both stems and flower stems (inflorescence) may be smooth to slightly hairy. The toothed, opposite leaves are 8-20 cm long and range from un-lobed to deeply three-lobed. The short leaf stalks are sometimes slightly winged. The 6-9 yellow ray-petals of the flowers are clustered at the ends of branches. Two rows of short, green, leaf-like involucre bracts (modified leaf) surround each head. Numerous tiny single-seeded fruits (achenes) develop on each head after flowering. Achenes are tan or brown coloured, 5-7 mm long and wedge-shaped, each with 2-4 barbed needle-like appendages (awns) that assist in seed dispersal by hooking onto fur, feathers or clothing.

Status

Global Status:	G3
Provincial Status:	S3
SARA Status:	Special Concern
BC List Status:	Blue (Considered to be of Special Concern)
